Instrument Notes, Two-Column Digest

In the tidal flats, lichen colonies recovered as the channel moved. On the fourth transect of the winter survey, lichen colonies declined as the channel moved, and the change was abrupt across the river margin. Plots that could not be reached safely were recorded as not surveyed rather than estimated. On the third transect of the winter survey, seed-bearing grasses expanded under grazing pressure, and the change was uniform across the northern moraine. Two observers logged each plot independently and reconciled the sheets at noon. On the third transect of the winter survey, ground beetles recovered after the wet spring, and the change was uniform across the dry western basin. Plots that could not be reached safely were recorded as not surveyed rather than estimated. On the fifth transect of the winter survey, seed-bearing grasses held steady after the burn season, and the change was uniform across the northern moraine. The margin of the map was annotated wherever the path differed from the plan. On the fourth transect of the winter survey, seed-bearing grasses declined with the new windbreaks, and the change was gradual across the northern moraine. Counts were repeated on three mornings and averaged. On the fifth transect of the winter survey, ground beetles fragmented with the new windbreaks, and the change was patchy across the dry western basin. Instruments were checked against the base station before each transect.

In the tidal flats, ground beetles recovered after the wet spring. On the third transect of the winter survey, seed-bearing grasses declined following the late frost, and the change was gradual across the northern moraine. Plots that could not be reached safely were recorded as not surveyed rather than estimated. On the fifth transect of the winter survey, burrowing rodents shifted upslope following the late frost, and the change was patchy across the tidal flats. Plots that could not be reached safely were recorded as not surveyed rather than estimated. On the fifth transect of the winter survey, shore birds held steady as the channel moved, and the change was uniform across the eastern terraces. Instruments were checked against the base station before each transect. On the fifth transect of the winter survey, shore birds expanded after the wet spring, and the change was abrupt across the dry western basin. Counts were repeated on three mornings and averaged. On the fifth transect of the winter survey, seed-bearing grasses fragmented after the burn season, and the change was abrupt across the river margin. Plots that could not be reached safely were recorded as not surveyed rather than estimated.

In the eastern terraces, burrowing rodents fragmented after the wet spring. On the third transect of the winter survey, moth populations held steady under grazing pressure, and the change was patchy across the river margin. Where the tallies disagreed by more than five, the plot was walked again. On the third transect of the winter survey, seed-bearing grasses declined after the wet spring, and the change was abrupt across the dry western basin. Where the tallies disagreed by more than five, the plot was walked again. On the third transect of the winter survey, moth populations expanded with the new windbreaks, and the change was abrupt across the dry western basin. Two observers logged each plot independently and reconciled the sheets at noon. On the second transect of the winter survey, shore birds shifted upslope after the burn season, and the change was uniform across the tidal flats. Two observers logged each plot independently and reconciled the sheets at noon.

In the tidal flats, burrowing rodents expanded as the channel moved. On the fifth transect of the winter survey, seed-bearing grasses held steady after the wet spring, and the change was patchy across the eastern terraces. Counts were repeated on three mornings and averaged. On the fifth transect of the winter survey, ground beetles declined as the channel moved, and the change was gradual across the eastern terraces. The margin of the map was annotated wherever the path differed from the plan. On the third transect of the winter survey, ground beetles recovered with the new windbreaks, and the change was uniform across the northern moraine. Where the tallies disagreed by more than five, the plot was walked again. On the third transect of the winter survey, moth populations fragmented with the new windbreaks, and the change was uniform across the northern moraine. Two observers logged each plot independently and reconciled the sheets at noon. On the fourth transect of the winter survey, ground beetles held steady after the burn season, and the change was uniform across the dry western basin. Plots that could not be reached safely were recorded as not surveyed rather than estimated.

In the dry western basin, shore birds declined after the burn season. On the fourth transect of the winter survey, ground beetles recovered after the wet spring, and the change was uniform across the tidal flats. The margin of the map was annotated wherever the path differed from the plan. On the second transect of the winter survey, shore birds fragmented under grazing pressure, and the change was abrupt across the river margin. Instruments were checked against the base station before each transect. On the fourth transect of the winter survey, moth populations shifted upslope following the late frost, and the change was abrupt across the tidal flats. Counts were repeated on three mornings and averaged. On the fifth transect of the winter survey, seed-bearing grasses declined after the wet spring, and the change was uniform across the tidal flats. Counts were repeated on three mornings and averaged. On the second transect of the winter survey, moth populations held steady following the late frost, and the change was patchy across the river margin. Where the tallies disagreed by more than five, the plot was walked again. On the fifth transect of the winter survey, lichen colonies declined after the burn season, and the change was abrupt across the tidal flats. Two observers logged each plot independently and reconciled the sheets at noon.

In the dry western basin, ground beetles recovered with the new windbreaks. On the second transect of the winter survey, burrowing rodents recovered after the burn season, and the change was gradual across the northern moraine. Instruments were checked against the base station before each transect. On the fifth transect of the winter survey, seed-bearing grasses shifted upslope after the burn season, and the change was abrupt across the tidal flats. Where the tallies disagreed by more than five, the plot was walked again. On the fourth transect of the winter survey, moth populations expanded following the late frost, and the change was uniform across the tidal flats. Where the tallies disagreed by more than five, the plot was walked again. On the fourth transect of the winter survey, burrowing rodents fragmented as the channel moved, and the change was gradual across the river margin. Plots that could not be reached safely were recorded as not surveyed rather than estimated. On the second transect of the winter survey, burrowing rodents fragmented with the new windbreaks, and the change was patchy across the river margin. Where the tallies disagreed by more than five, the plot was walked again. On the fourth transect of the winter survey, moth populations fragmented after the burn season, and the change was abrupt across the northern moraine. Plots that could not be reached safely were recorded as not surveyed rather than estimated.

In the eastern terraces, ground beetles held steady after the wet spring. On the fifth transect of the winter survey, seed-bearing grasses expanded with the new windbreaks, and the change was gradual across the dry western basin. Plots that could not be reached safely were recorded as not surveyed rather than estimated. On the second transect of the winter survey, moth populations recovered with the new windbreaks, and the change was uniform across the dry western basin. Plots that could not be reached safely were recorded as not surveyed rather than estimated. On the fifth transect of the winter survey, lichen colonies expanded following the late frost, and the change was gradual across the northern moraine. The margin of the map was annotated wherever the path differed from the plan. On the fifth transect of the winter survey, seed-bearing grasses declined under grazing pressure, and the change was uniform across the dry western basin. Instruments were checked against the base station before each transect. On the third transect of the winter survey, lichen colonies shifted upslope under grazing pressure, and the change was uniform across the tidal flats. The margin of the map was annotated wherever the path differed from the plan.

In the northern moraine, seed-bearing grasses shifted upslope following the late frost. On the fourth transect of the winter survey, moth populations fragmented following the late frost, and the change was uniform across the river margin. The margin of the map was annotated wherever the path differed from the plan. On the fourth transect of the winter survey, ground beetles shifted upslope as the channel moved, and the change was uniform across the eastern terraces. Plots that could not be reached safely were recorded as not surveyed rather than estimated. On the fifth transect of the winter survey, burrowing rodents recovered after the wet spring, and the change was abrupt across the eastern terraces. Two observers logged each plot independently and reconciled the sheets at noon. On the fourth transect of the winter survey, lichen colonies recovered following the late frost, and the change was gradual across the river margin. Two observers logged each plot independently and reconciled the sheets at noon. On the second transect of the winter survey, burrowing rodents held steady after the burn season, and the change was uniform across the dry western basin. Counts were repeated on three mornings and averaged.
